◆ AI Overview

There is **no official GNU version of the `mount` command** available via standard macOS package managers. GitHub

The standard `mount` command found on Linux systems is actually part of the `util-linux` package (maintained by the Linux Kernel Archive), rather than the GNU Project. While Homebrew provides a `util-linux` package, its version of `mount` is explicitly excluded on macOS because it relies on low-level Linux kernel APIs that are completely incompatible with the macOS Darwin kernel. Stack Exchange +2

If you are trying to solve a specific problem, consider these native macOS alternatives:

macOS Native Mounting Alternatives

- **For Standard Volumes:** Use the native macOS command `diskutil mount /dev/diskXsY` or the native BSD version of `mount` already built into your system.
- **For Disk Images (.dmg or .iso):** Use the native tool `hdiutil attach image.dmg`.
- **For Linux Filesystems (ext4):** Use [anylinuxfs](#) via Homebrew to run a lightweight virtual machine that bridges Linux filesystems to macOS.
- **For Network Shares:** Use `mount_smbfs` for Windows/Samba shares or `mount_nfs` for network file systems. GitHub +4

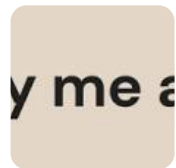

What **type of filesystem or drive** are you trying to mount? If you share your end goal, I can provide the exact command or tool you need for macOS.
