

git commit stopped working - Error building trees

Asked 13 years, 8 months ago Modified yesterday Viewed 97k times

I can not commit a change:

119

```
$ git commit
error: invalid object 100644 13da9eef5a9150cf2135aaed4d2e337f97b8114 for
'spec/routing/splits_routing_spec.rb'
error: Error building trees
```

I tried so far:

```
$ git fsck | grep 13da
missing blob 13da9eef5a9150cf2135aaed4d2e337f97b8114
```

and also:

```
$ git prune
error: Could not read 1394dce6fd1ad15a70b2f2623509082007dc5b6c
fatal: bad tree object 1394dce6fd1ad15a70b2f2623509082007dc5b6c
```

and also:

```
$ git fsck | grep 13da
missing blob 13da9eef5a9150cf2135aaed4d2e337f97b8114
```

but nothing helped. Should I delete the file, commit and reintroduce back? I am willing to lose little bit of history if it brings git commit back.

This error means that you have a file with hash `13da9eef5a9150cf2135aaed4d2e337f97b8114` , and this hash is not present in `.git/objects/./` , or it's empty.

198 You just need to generate the object hash:

```
git hash-object -w spec/routing/splits_routing_spec.rb
```

For more information see [documentation](#). In the documentation, there is an additional way of repairing this error.

P.S. This was the only way that was helpful for me.

i did this and it works, but the error reaccures next time i try to commit, any solve that is permanant?

▲ 2

Reply

Alex Nikulin Over a year ago

@NotSoShabby maybe is the problem with your hdd. your meta file is corrupted by some process or hardware problem.

▲ 0

Reply

user1097111 Over a year ago

There were multiple corrupted files for me and after running the above command on all files, git still generated a fatal error without pointing to a particular file. I run "git hash-object -t ." to regenerate the hash for all files, and then it was fine.

Before anyone does git reset --hard know it will make you lose all uncommitted changes!!

▲ 1

Reply

You might have a corrupted object in your git repository.

23

If you have a remote, or other clones of this repository, you could grab from there the problematic file and just replace it on your local repo.

The file you want would be in:

/repo/.git/objects/13/da9eeff5a9150cf2135aaed4d2e337f97b8114

in my case, the file referenced is no longer in the .git objects folder! >.<

4

Reply

[fuzzyTew](#) Over a year ago

Exactly: you want to look for it in other clones of the repo, where it may exist

Reply

[Simon C.](#) Over a year ago

Had the same problem due to I/O error. I wasn't able to replace the file but I removed the whole folder (in the example given it would be /local/.git/objects/13/) and I copied a copy of it from my remote repo. It did the trick and all is working back again! thanks

[sagannotcarl](#) Over a year ago

The answer below by @AlexNikulin is an even better solution: `git hash-object -w spec/routing/splits_routing_spec.rb`

9

Reply

[Nikos Alexandris](#) Over a year ago

I downvoted this answer because the `git hash-object -w` worked better (for me).

7

Reply

`git reset --hard` should bring your repository back to normal, but you will lose uncommitted changes.

+1 reset --hard worked for me. my issue is Google Drive syncing my local code across multiple machines - you have to remember to stop and restart it to let it sync up. I think google drive must purposely ignore monitoring .git directories cause of the mass changes.

A simple trick mentioned in [this](#) Medium article solved my case where I ran into similar 'invalid object' & 'error building tree' issues. The solution is pretty straightforward:

```
git hash-object -w <file-name-which-is-creating-problem>
```

After that, git will make a Sha1 for the file whose hashes were not matching and its repository will be fixed.

Now I can use `git add *` and `git commit -m` without any issues. That's it.

Note: Create a copy (aka backup) incase if you are not sure what you are doing.

If the problematic file is being added by your change you can just remove it from the index and add it again:

```
git reset <file>
git add <file>
```

This doesnt work if the file is now missing from your disk drive; because there is no physical file to reset, you get a `fatal: ambiguous argument 'path/to/file.ext': unknown revision or path not in the working tree.` message

4

Reply

For me it was just permissions issue. When I run with `sudo`, it worked. perhaps something to do with mac environment

`sudo` is a bit too permissive, but it was indeed a permission problems. Fixed it by restoring ownership of the whole folder to the proper user.

Easy work around solution, if you're not really concerned on the track of the file, you can duplicate the file and remove the original, commit first the deletion and addition, then rename to original again.

Git should build back again normally

This can be caused by some third-party synchronization APP such as Dropbox and Jianguoyun. There might be two ways based on my experience:

1. You can try to undo recent synchronization operations.
2. Remove the related files from the folder, commit, and then move back the files.

How do I find out which files are related? `git gc` doesn't give me any more info.

▲ 0 [Reply](#) [...](#)

Tim Kuipers Over a year ago

I have Dropbox and it messed up some internal `.git` file somewhere, but I don't know when and it wasn't related to any already committed file, but to my uncommitted changes. I just had to change my text/code a little bit, so that the hash would be different and the error wouldn't be triggered anymore.

In my case, it is the file in remote branch that is broken. I solved it by:

1. remove the remote branches at all by `$ git remote rm origin`
2. add the remote back again: `$ git remote add origin <the-remote-url>`
3. fetch the remote again: `$ git fetch origin`
4. reset-hard to the desired branch on origin (say, `develop`): `$ git reset --hard origin/develop`

Then everything goes back to normal.

In my case, this was due to a different version of git. I had been using my repository through the official Windows port of git and started using the MinGW port with the same version number.

I started to encounter this issue when trying to commit with MinGW git. Switching back to windows Git solved the issue.

it's as simple as cloning from the remote repo to a new folder, deleting all the files on this new folder keeping the .git one. And then copying all the files from the old folder to the new cloned folder without copying the .git folder..

well I faced this issue also, what i did is: copy changed folder or files to another project in VSCode and delete that repository and clone again and pass that file(s) or folder(s) back again. looks like long way but i think it is better to make sure u won't lose your files that u didn't commit yet

The easiest way to tackle this issue is :

1. Copy the uncommit files.
2. Then use `$ git reflog -1`
3. use `$ git reset --hard xxxxxx` (xxxxx your last commit head)
4. Then paste your files again.

It's worked for me. No need to clone the repo or remove the remote.

git status

0

and then it shows you which files were modified/causing the issue... then you can either add them via `git add "filename"` - without the quotes or remove via `git rm "filename"`

error: invalid object 100644 d5b87de7ffab13b0f9669abceae5c5193ac950ec for 'angular.json'
error: invalid object 100644 d5b87de7ffab13b0f9669abceae5c5193ac950ec for 'angular.json'
error: Error building trees

0

I faced this issue. Here's how I fixed it.

- I cloned the repository again (to get a "fresh" copy)

- I copied the entire `.git` folder from the cloned repository

- Deleted the `.git` folder from the original repository with the error

- Pasted the new `.git` folder in the original repository

It works!

I hope this will be helpful to someone else!

If your repository is synced using OneDrive and none of the above solutions work (git commands result in more errors), it might be a [bug with OneDrive app](#). Suggested solution (which worked for me) is to scan and fix your hard drive:

1. Search `Command Prompt` in the Start menu
2. Right click on `Command Prompt` > `Run as administrator`
3. Enter command `chkdsk \r \f`
4. If `chkdsk` is unable to scan and fix the drive immediately, it'll ask to perform the operation during next restart - confirm that you want to scan the drive
